

1. Find Lagrangian coordinates $\vec{x}(\vec{a}, t, t_0)$ for the following Eulerian velocity fields. In each case express your answer as functions $x(a, b, t), y(a, b, t)$:

$$(a) \quad u = x, v = -y; \quad (b) \quad u = y + t^2, v = -x$$

In each case find the equations for the streamlines, particle paths, and streak lines. Sketch the particle path for the particle which is at $(a, b) = (1, 1)$ when $t = t_0 = 1$, and the streak line from $(a, b) = (1, 1)$ obtained for $t_0 < t = 0$. In (a), verify that streamlines and particle paths coincide.

2. Consider the “point vortex ” flow in two dimensions,

$$(u, v) = UL \left(\frac{-y}{x^2 + y^2}, \frac{x}{x^2 + y^2} \right), \quad x^2 + y^2 \neq 0,$$

where U, L are reference values of speed and length. (a) Show that the Lagrangian coordinates for this flow may be written

$$x(a, b, t) = R_0 \cos(\omega t + \theta_0), \quad y(a, b, t) = R_0 \sin(\omega t + \theta_0)$$

where $R_0^2 = a^2 + b^2, \theta_0 = \arctan(b/a)$, and $\omega = UL/R_0^2$. (b) Consider, at $t = 0$ a small rectangle of marked fluid particles determined by the points $A(L, 0), B(L + \Delta x, 0), C(L + \Delta x, \Delta y), D(L, \Delta y)$. If the points move with the fluid, once point A returns to its initial position what is the shape of the marked region? Since $(\Delta x, \Delta y)$ are small, you may assume the region remains a parallelogram. Do this, first, by computing the entry $\partial y / \partial a$ in the jacobian, evaluated at $A(L, 0)$. Then verify your result by considering the “lag” of particle B as it moves on a slightly larger circle at a slightly slower speed, relative to particle A , for a time taken by A to complete one revolution.

3. As was noted in class, Lagrangian coordinates can use any unique labeling of fluid particles. To illustrate this, consider the Lagrangian coordinates in two dimensions

$$x(a, b, t) = a + \frac{1}{k} e^{kb} \sin k(a + ct), \quad y = b - \frac{1}{k} e^{kb} \cos k(a + ct),$$

where k, c are constants. Note here a, b are *not* equal to (x, y) for any t_0 . By examining the determinant of the Jacobian, verify that this gives a unique labeling of fluid

particles provided that $b \neq 0$. What is the situation if $b = 0$? (These waves, which were discovered by Gerstner in 1802, represent gravity waves if $c^2 = g/k$ where g is the acceleration of gravity. They do not have any simple Eulerian representation. These waves are discussed in Lamb's book.)

4. In one dimension, the Eulerian velocity is given to be $u(x, t) = 2x/(1 + t)$. (a) Find the Lagrangian coordinate $x(a, t)$. (b) Find the Lagrangian velocity as a function of a, t . (c) Find the jacobian $\partial x/\partial a = J$ as a function of a, t . (d) If density satisfies $\rho(x, 0) = x$ and mass is conserved, find $\rho(a, t)$ using the Lagrangian form of mass conservation. (e) From (a) and (d) evaluate ρ as a function of x, t , and verify that the Eulerian conservation of mass equation is satisfied by $\rho(x, t), u(x, t)$.

5. For the stagnation-point flow $\vec{u} = (u, v) = U/L(x, -y)$, show that a fluid particle in the first quadrant which crosses the line $y = L$ at time $t = 0$, crosses the line $x = L$ at time $t = \frac{L}{U} \log(UL/\psi)$ on the streamline $Uxy/L = \psi$. Do this in two ways. First, consider the line integral of $\vec{u} \cdot \vec{ds}/(u^2 + v^2)$ along a streamline. Second, use lagrangian variables.

6. Let V_t denote a fluid volume in three-dimensions. Prove that, for any smooth function $\vec{g}(\vec{x}, t)$,

$$\frac{d}{dt} \int \rho \vec{g} dV_t = \int \rho D\vec{g}/Dt dV_t.$$

Here ρ is the density, satisfying the mass conservation equation $\rho_t + \nabla \cdot (\rho \vec{u}) = 0$, and $D/Dt = \frac{\partial}{\partial t} + \vec{u} \cdot \nabla$. (Hint: $dV_t = \det(\mathbf{J})dV_0$ from the result for $\det(\mathbf{J})$ proved in class.)
